Saved PR2 clarification email

Subject: IBEHS 5P06 - Team 19 PR2 revisions and deadline clarification

Hello Dr. Leung, Dr. Smith, and/or the IBEHS 5P06 teaching team,

We are writing about Team 19's Progress Report 2 feedback and the required resubmission. We understood "before PR3" as work we could address through ongoing discussions before the next report. Today we noticed the one-week resubmission requirement. Since we received feedback on November 3, that would make the resubmission due November 10. We apologize for the misunderstanding and late clarification.

Does November 10 apply, or may we complete the revisions before PR3 on December 11? If November 10 applies, could we please have until Friday, November 13, with confirmation of what must be included then?

I contacted the teaching assistants first because the progress report instructions say they grade the reports, but the TA who replied said this was not their responsibility.

The proposed revised PR2 is attached, with changes highlighted in yellow:

1. Supervisor agreement: Section 3.1 compares existing wearables, phone-based monitoring and custom sensing by data access, data quality, patient comfort and practicality, setup, cost and development effort. The initial choice can be revised as evidence develops. Could you confirm this comparison process is acceptable?

2. Table 1 separates the provisional target for the software test from limits that still need evidence. With your agreement to section 3.1, would this revised PR2 meet the requirements for a Pass, with the remaining performance and usability targets and tests covering noise and ordinary movement completed before PR3? If not, can you please specify what must be completed for PR2 to pass.

3. The attached revision adds the requested likelihood and severity assessments to prioritize the risks and updates the title to reflect monitoring.

4. Section 3.2 outlines an initial proof of concept for processing motion data and displaying tremor measurements and whether the data are usable. Evaluation may use simulated signals or suitable recordings, with methods refined as the concept develops. Would this approach satisfy the requested tests covering noise and ordinary movement, while explaining what the results do and do not demonstrate?

Monitoring remains our core deliverable, with electrical stimulation as an option we are continuing to investigate.

Thank you for your time.

Imran Chowdhury
